

The MAX4310-MAX4315 single-supply mux-amps combine high-speed operation, low-glitch switching, and excellent video specifications. The six products in this family are differentiated by the number of multiplexer inputs and the gain configuration. The MAX4310/ MAX4311/MAX4312 integrate 2-/4-/8-channel multiplexers, respectively, with an adjustable gain amplifier optimized for unity-gain stability. The MAX4313/MAX4314/ MAX4315 integrate 2-/4-/8-channel multiplexers, respectively, with a $+2 \mathrm{~V} / \mathrm{N}$ fixed-gain amplifier. All devices have 40ns channel switching time and low 10 mV p-p switching transients, making them ideal for video-switching applications. They operate from a single +4 V to +10.5 V supply, or from dual supplies of $\pm 2 \mathrm{~V}$ to $\pm 5.25 \mathrm{~V}$, and they feature rail-to-rail outputs and an input common-mode voltage range that extends to the negative supply rail.
The MAX4310/MAX4311/MAX4312 have a -3dB bandwidth of $280 \mathrm{MHz} / 345 \mathrm{MHz} / 265 \mathrm{MHz}$ and up to a $460 \mathrm{~V} / \mathrm{us}$ slew rate. The MAX4313/MAX4314/MAX4315, with $150 \mathrm{MHz} / 127 \mathrm{MHz} / 97 \mathrm{MHz}-3 \mathrm{~dB}$ bandwidths up to a $540 \mathrm{~V} / \mathrm{us}$ slew rate, and a fixed gain of $+2 \mathrm{~V} / \mathrm{N}$, are ideally suited for driving back-terminated cables. Quiescent supply current is as low as 6.1 mA , while low-power shutdown mode reduces supply current to as low as $560 \mu \mathrm{~A}$ and places the outputs in a high-impedance state. The MAX4310-MAX4315's internal amplifiers maintain an open-loop output impedance of only $8 \Omega$ over the full output voltage range, minimizing the gain error and bandwidth changes under loads typical of most rail-to-rail amplifiers. With differential gain and phase errors of $0.06 \%$ and $0.08^{\circ}$, respectively, these devices are ideal for broadcast video applications.

|  | Applications |
| :--- | :--- |
| Video Signal Multiplexing | Broadcast Video |
| Video Crosspoint Switching | Medical Imaging |
| Flash ADC Input Buffers | Multimedia Products |
| $75 \Omega$ Video Cable Drivers |  |
| High-Speed Signal Processing |  |

Video Signal Multiplexing Video Crosspoint Switching Flash ADC Input Buffers $75 \Omega$ Video Cable Drivers High-Speed Signal Processing

- Single-Supply Operation Down to +4 V
- 345MHz -3dB Bandwidth (MAX4311) $150 \mathrm{MHz}-3 \mathrm{~dB}$ Bandwidth (MAX4313)
- 540V/ $\mu \mathrm{s}$ Slew Rate (MAX4313)
- Low 6.1 mA Quiescent Supply Current
- 40ns Channel Switching Time
- Ultra-Low 10 mVp -p Switching Transient
- 0.06\%/0.08 ${ }^{\circ}$ Differential Gain/Phase Error
- Rail-to-Rail Outputs: Drives $150 \Omega$ to within 730 mV of the Rails
- Input Common-Mode Range Includes Negative Rail
- Low-Power Shutdown Mode
- Available in Space-Saving 8-Pin $\mu$ MAX ${ }^{\circledR}$ and 16-Pin QSOP Packages

## Ordering Information

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

#### Abstract

Detailed Description The MAX4310/MAX4311/MAX4312 combine 2-channel, 4-channel, or 8-channel multiplexers, respectively, with an adjustable-gain output amplifier optimized for closed-loop gains of $+1 \mathrm{~V} / \mathrm{V}(0 \mathrm{~dB})$ or greater. The MAX4313/MAX4314/MAX4315 combine 2-channel, 4channel, or 8-channel multiplexers, respectively, with a $+2 \mathrm{~V} / \mathrm{V}(6 \mathrm{~dB})$ fixed-gain amplifier, optimized for driving back-terminated cables. These devices operate from a single supply voltage of +4 V to +10.5 V , or from dual supplies of $\pm 2 \mathrm{~V}$ to $\pm 5.25 \mathrm{~V}$. The outputs may be placed in a high-impedance state and the supply current minimized by forcing the SHDN pin low. The input multiplexers feature short 40ns channel-switching times and small $10 \mathrm{mVp}-\mathrm{p}$ switching transients. The input capacitance remains constant at 1 pF whether the channel is on or off, providing a predictable input impedance to the signal source. These devices feature single-supply, rail-to-rail, voltage-feedback output amplifiers that achieve up to $540 \mathrm{~V} / \mu$ s slew rates and up to 345 MHz $-3 d B$ bandwidths. These devices also feature excellent harmonic distortion and differential gain/phase performance.

## Applications Information

Rail-to-Rail Outputs, Ground-Sensing Input The input common-mode range extends from the negative supply rail to Vcc -2.7 V with excellent commonmode rejection. Beyond this range, multiplexer switching times may increase and the amplifier output is a nonlinear function of the input, but does not undergo phase reversal or latchup.
The output swings to within 250 mV of VCC and 40 mV of $V_{E E}$ with a $10 \mathrm{k} \Omega$ load. With a $150 \Omega$ load to ground, the output swings from 30 mV above $\mathrm{V}_{\mathrm{EE}}$ to within 730 mV of

Figure 1. MAX4310 Noninverting Gain Configuration
the supply rail. Local feedback around the output stage ensures low open-loop output impedance to reduce gain sensitivity to load variations. This feedback also produces demand-driven bias current to the output transistors for $\pm 95 \mathrm{~mA}$ drive capability while constraining total supply current to only 6.1 mA .

## Feedback and Gain Resistor Selection <br> (MAX4310/MAX4311/MAX4312)

Select the MAX4310/MAX4311/MAX4312 gain-setting feedback ( $R_{F}$ ) and input ( $R_{G}$ ) resistors to fit your application. Large resistor values increase voltage noise and interact with the amplifier's input and PC board capacitance. This can generate undesirable poles and zeros, and can decrease bandwidth or cause oscillations. For example, a noninverting gain of $+2 \mathrm{~V} / \mathrm{N}$ configuration ( $\mathrm{RF}_{\mathrm{F}}=$ $R G$ ) using $1 \mathrm{k} \Omega$ resistors, combined with 2 pF of input capacitance and 1 pF of PC board capacitance, causes a pole at 159 MHz . Since this pole is within the amplifier bandwidth, it jeopardizes stability. Reducing the $1 \mathrm{k} \Omega$ resistors to $100 \Omega$ extends the pole frequency to 1.59 GHz , but could limit output swing by adding $200 \Omega$ in parallel with the amplifier's load resistor.
Table 1 shows suggested RF and RG values for the MAX4310/MAX4311/MAX4312 when operating in the noninverting configuration (shown in Figure 1). These values provide optimal AC response using surface-mount resistors and good layout techniques, as discussed in the Layout and Power-Supply Bypassing section.
Stray capacitance at the FB pin causes feedback resistor decoupling and produces peaking in the frequencyresponse curve. Keep the capacitance at FB as low as possible by using surface-mount resistors and by avoiding the use of a ground plane beneath or beside these resistors and the FB pin. Some capacitance is unavoidable; if necessary, its effects can be neutralized by adjusting RF. Use $1 \%$ resistors to maintain consistency over a wide range of production lots.

Table 1. Bandwidth and Gain with Suggested Gain-Setting resistors (MAX4310/MAX4311/MAX4312)

| GAIN <br> $(\mathbf{V} / \mathbf{V})$ | GAIN <br> $\mathbf{( d ~ B )}$ | $\mathbf{R}_{\mathbf{F}}$ <br> $(\Omega)$ | $\mathbf{R}_{\mathbf{G}}$ <br> $(\Omega)$ | $-3 \mathrm{3dB} \mathbf{B W}$ <br> $\mathbf{( M H z )}$ | $\mathbf{0 . 1 d B} \mathbf{~ B W}$ <br> $(\mathbf{M H z})$ |
| :---: | :---: | :---: | :---: | :---: | :---: |

| 10 | 20 | 500 | 56 | 10 | 2 |

## High－Speed，Low－Power，Single－Supply Multichannel，Video Multiplexer－Amplifiers

Figure 2．Logic－Low Input Current vs．VIL（ $\overline{S H D N}, A 0, A 1, ~ A 2)$

Figure 3．Circuit to Reduce Logic－Low Input Current

## Low－Power Shutdown Mode

All parts feature a low－power shutdown mode that is activated by driving the SHDN input low．Placing the amplifier in shutdown mode reduces the quiescent sup－ ply current to $560 \mu \mathrm{~A}$ and places the output into a high－ impedance state，typically $35 \mathrm{k} \Omega$ ．By tying the outputs of several devices together and disabling all but one of the paralleled amplifiers＇outputs，multiple devices may be paralleled to construct larger switch matrices．
For MAX4310／MAX4311／MAX4312 application circuits operating with a closed－loop gain of $+2 \mathrm{~V} / \mathrm{V}$ or greater， consider the external－feedback network impedance of all devices used in the mux application when calculat－ ing the total load on the output amplifier of the active device．The MAX4313／MAX4314／MAX4315 have a fixed gain of $+2 \mathrm{~V} / \mathrm{V}$ that is internally set with two $500 \Omega$ thin－ film resistors．The impedance of the internal feedback resistors must be taken into account when operating multiple MAX4313／MAX4314／MAX4315s in large multi－ plexer applications．For normal operation，drive SHDN high．If the shutdown function is not used，connect $\overline{\text { SHDN }}$ to Vcc．

Figure 4．Logic－Low Input Current vs．VIL with $10 k \Omega$ Series Resistor

Layout and Power－Supply Bypassing The MAX4310－MAX4315 have very high bandwidths and consequently require careful board layout，including the possible use of constant－impedance microstrip or stripline techniques．
To realize the full AC performance of these high－speed amplifiers，pay careful attention to power－supply bypass－ ing and board layout．The PC board should have at least two layers：a signal and power layer on one side，and a large，low－impedance ground plane on the other side． The ground plane should be as free of voids as possible， with one exception：the feedback（FB）should have as low a capacitance to ground as possible．Therefore，layers that do not incorporate a signal or power trace should not have a ground plane．
Whether or not a constant－impedance board is used，it is best to observe the following guidelines when designing the board：
1）Do not use wire－wrapped boards（they are too inductive）or breadboards（they are too capacitive）．
2）Do not use IC sockets；they increase parasitic capacitance and inductance．
3）Keep signal lines as short and straight as possible． Do not make $90^{\circ}$ turns；round all corners．
4）Observe high－frequency bypassing techniques to maintain the amplifier＇s accuracy and stability．
5）Use surface－mount components．They generally have shorter bodies and lower parasitic reactance， yielding better high－frequency performance than through－hole components．

Figure 7. Using an Isolation Resistor (RISO) for High-Capacitive Loads

Figure 8. Optimal Isolation Resistance vs. Capacitive Load

Figure 9. Small-Signal Gain vs. Frequency with a Capacitive Load and $27 \Omega$ No-Isolation Resistor

The bypass capacitors should include a 100 nF , ceramic surface-mount capacitor between each supply pin and the ground plane, located as close to the package as possible. Optionally, place a $10 \mu \mathrm{~F}$ tantalum capacitor at the power-supply pin's point of entry to the PC board to ensure the integrity of incoming supplies. The power-supply trace should lead directly from the tantalum capacitor to the VCC and VEE pins. To minimize parasitic inductance, keep PC traces short and use sur-face-mount components. If input termination resistors and output back-termination resistors are used, they should be surface-mount types, and should be placed as close to the IC pins as possible.

## High-Speed, Low-Power, Single-Supply Multichannel, Video Multiplexer-Amplifiers

Figure 10. High-Speed EV Board Layout-Component Side

Figure 11. High-Speed EV Board Layout-Solder Side
Video Line Driver
The MAX4310-MAX4315 are well-suited to drive coaxial transmission lines when the cable is terminated at both ends, as shown in Figure 5. Cable frequency response can cause variations in the signal's flatness.

## Driving Capacitive Loads

A correctly terminated transmission line is purely resistive and presents no capacitive load to the amplifier. Reactive loads decrease phase margin and may produce excessive ringing and oscillation (see Typical Operating Characteristics).

| 1 | 1 | 0 | 1 | 5 |
| 1 | 1 | 1 | 0 | 6 |
| 1 | 1 | 1 | 1 | 7 |

Another concern when driving capacitive loads originates from the amplifier's output impedance, which appears inductive at high frequencies. This inductance forms an L-C resonant circuit with the capacitive load, which causes peaking in the frequency response and degrades the amplifier's phase margin.
Although the MAX4310-MAX4315 are optimized for AC performance and are not designed to drive highly capacitive loads, they are capable of driving up to 20 pF without oscillations. However, some peaking may occur in the frequency domain (Figure 6). To drive larger capacitive loads or to reduce ringing, add an isolation resistor between the amplifier's output and the load (Figure 7).
The value of RISO depends on the circuit's gain and the capacitive load (Figure 8). Figure 9 shows the MAX4310-MAX4315 frequency response with the isolation resistor and a capacitive load. With higher capacitive values, bandwidth is dominated by the RC network formed by RISO and CL; the bandwidth of the amplifier itself is much higher. Also note that the isolation resistor forms a divider that decreases the voltage delivered to the load.

# High-Speed, Low-Power, Single-Supply Multichannel, Video Multiplexer-Amplifiers 

## Digital Interface

The multiplexer architecture of the MAX4310-MAX4315 ensures that no two input channels are ever connected together. Channel selection is accomplished by applying a binary code to channel address inputs. The address decoder selects input channels, as shown in Table 2. All digital inputs are CMOS compatible.

## High-Speed Evaluation Board

Figures 10 and 11 show the evaluation board and present a suggested layout for the circuits. This board was developed using the techniques described in the Layout and Power-Supply Bypassing section. The smallest available surface-mount resistors were used
for feedback and back-termination to minimize their distance from the part, reducing the capacitance associated with longer lead lengths.
SMA connectors were used for best high-frequency performance. Inputs and outputs do not match a $75 \Omega$ line, but this does not affect performance since distances are extremely short. However, in applications that require lead lengths greater than one-quarter of the wavelength of the highest frequency of interest, use constant-impedance traces. Fully assembled evaluation boards are available for the MAX4313 in an SO package.
