

**DESCRIPTION**

This document describes the specification for the F1956 Digital Step Attenuator. The F1956 is part of Renesas' *Glitch-Free™* family of DSAs optimized for the demanding requirements of Base Station (BTS) radio cards and numerous other non-BTS applications. This device is offered in compact 5 x 5 mm 32-pin package with 50Ω input and output impedance for ease of integration into the radio or RF system.

**COMPETITIVE ADVANTAGE**

The F1956 offers very high reliability due to its construction from a monolithic silicon die in a QFN package. The insertion loss is very low with minimal distortion. Additionally the device is designed to have extremely accurate attenuations levels. These accurate attenuation level improves system SNR and/or ACLR by ensuring system gain is as close to targeted level as possible. Also, the very fast settling time in parallel mode is ideal for fast switching systems. Finally, the device is *Glitch-Free™* with less than 2dB of ringing across the attenuation range in stark contrast to competing DSAs that glitch as much as 10dB during MSB state changes.

- ✓ Lowest insertion loss for best SNR
- ✓ *Glitch-Free™* technology to protect PA or ADC during transitions between attenuation states.
- ✓ Extremely accurate attenuation levels
- ✓ Ultra low distortion
- ✓ MSL1 and 2000V HBM ESD

**FEATURES**

- Serial and 7-bit Parallel Interface
- 31.75dB Range
- 0.25dB steps
- *Glitch-Free™*: low transient overshoot
- 500ns settling time
- Ultra linear > 64dBm IIP3
- Low Insertion Loss < 1.7dB at 4GHz
- Attenuation error < ±0.2dB at 4GHz
- Bi-directional RF use
- 3.3V or 5V Supply
- 1.8V or 3.3V control logic
- Low Current Consumption: 350µA typical
- -40°C to +105°C operating temperature
- 5 x 5 mm thin [32-QFN](#) package

## PROGRAMMING OPTIONS

F1956 can be programmed using either the parallel or serial interface; selectable via  $V_{MODE}$  (pin 3). Serial mode is selected by floating  $V_{MODE}$  or pulling  $V_{MODE}$  to a logic high and parallel mode is selected by setting  $V_{MODE}$  to logic low.

## SERIAL CONTROL MODE

F1956 Serial mode is selected by floating  $V_{MODE}$  (pin 3) or pulling it to logic high. The serial interface is a 16-bit shift register made up of two words. The first 8-bit word is the Attenuation word, which controls the DSA state. The second word is the address word, which uses only 3 of 8-bits that must match the hard wired A0-A2 programming in order to change the DSA state. If no external connections are made to A0 – A2 then internally they will default to 000 due to internal pull down resistors. If these 3 external preset address bits are not matched with the SPI loaded address bits then the current attenuator state will remain unchanged. This allows up to 8 serial-controlled devices to be used on a single board, which share a common DATA, CLK and LE.

When serial programming is used, all the parallel control input pins 26 – 32 can be left open or grounded. If a pin is grounded then an additional 25 $\mu$ A will be drawn from the voltage supply per pin.

**REGISTER TIMING DIAGRAM: (NOTE THE TIMING SPEC INTERVALS IN BLUE)**

With serial control, the F1956 can be programmed via the serial port on the rising edge of Latch Enable (LE) which loads the last 8 DATA line bits [formatted LSB (D0) first] resident in the SHIFT register followed by the Address Word into the ACTIVE register.

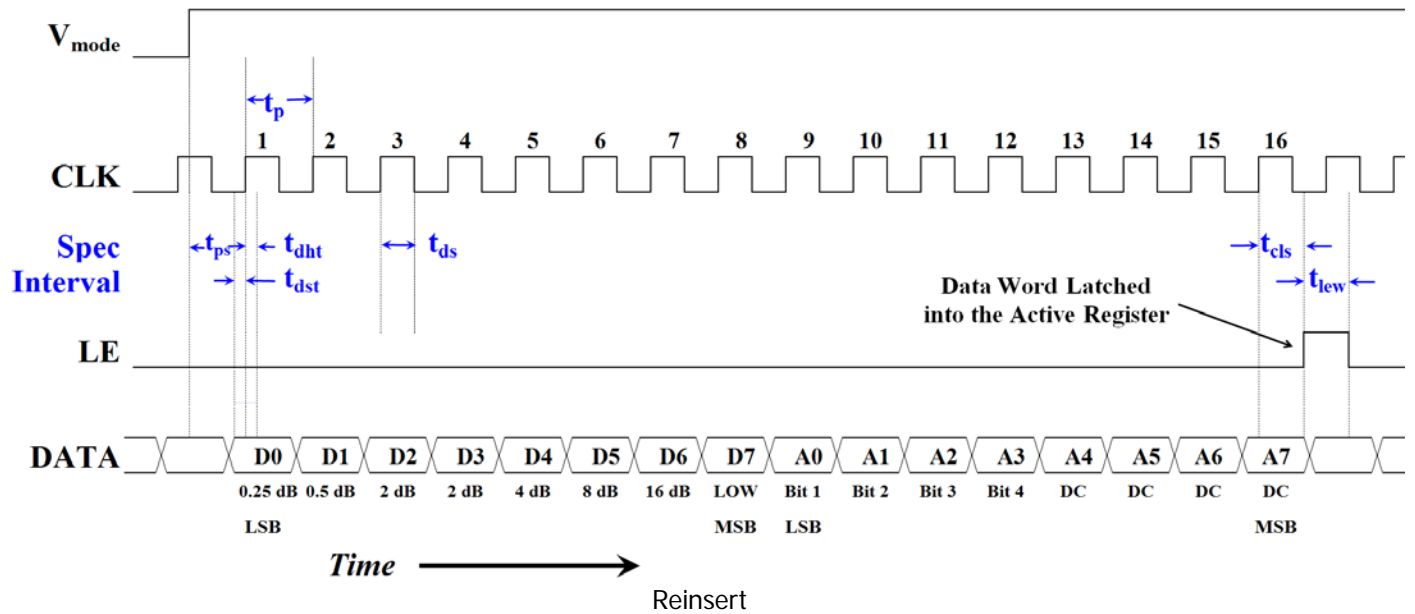

Figure 4. Serial Timing Diagram

Note - When Latch enable is high, the shift register is disabled and DATA is NOT continuously clocked into the shift register which minimizes noise. It is recommended that Latch enable be left high when the device is not being programmed.

### PARALLEL CONTROL MODE

For the F1956 the user has the option of running in one of two parallel modes. Direct Parallel Mode or Latched Parallel Mode.

#### Direct Parallel Mode:

Direct Parallel Mode is selected when V<sub>MODE</sub> is a logic low and LE is a logic high. In this mode the device will immediately react to any voltage changes to the parallel control pins [pins 26 – 32]. Use direct parallel mode for the fastest settling time.

**Latched Parallel Mode:**

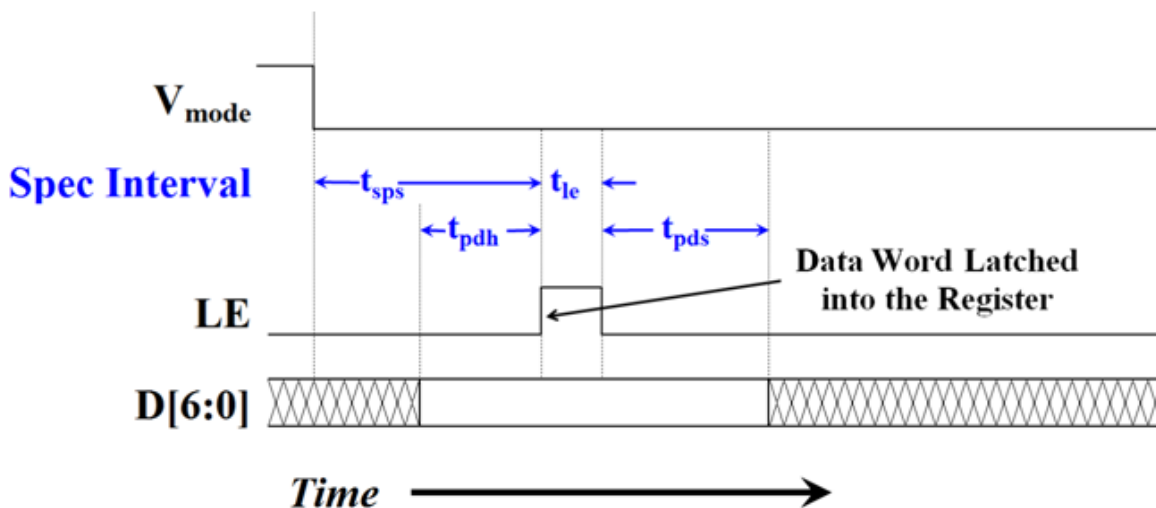

Latched Parallel Mode is selected when  $V_{MODE}$  is logic low and LE is toggled from logic low to high. To utilize Latched Parallel Mode:

- Set  $V_{MODE}$  is logic low.
- Set LE to logic low.
- Adjust pins [26, 27, 28, 29, 30, 31, 32] to the desired attenuation setting. (Note the device will not react to these pins while LE is a logic low).
- Pull LE to a logic high. The device will then transition to the attenuation settings reflected by pins D6 - D0.
- IF LE is pulled to a logic low then the attenuator will not change state.

Latched Parallel Mode implies a default state for when the device is first powered up with  $V_{MODE}$  set for logic low and LE logic low. In this case the default setting is MAXIMUM Attenuation.

## TOP MARKINGS

## APPLICATIONS INFORMATION

### Power Supplies

A common  $V_{DD}$  power supply should be used for all pins requiring DC power. All supply pins should be bypassed with external capacitors to minimize noise and fast transients. Supply noise can degrade noise figure and fast transients can trigger ESD clamps and cause them to fail. Supply voltage change or transients should have a slew rate smaller than  $1V/20\mu s$ . In addition, all control pins should remain at 0V ( $\pm 0.3V$ ) while the supply voltage ramps or while it returns to zero.

### Digital Pin Voltage and Resistance Values

The following table provides open-circuit DC voltage referenced to ground and resistance values for each of the control pins listed.

Pin	Name	Open Circuit DC Voltage	Internal Connection
3	$V_{MODE}$	2.5V	100k $\Omega$ pull-up resistor to internally regulated 2.5V
4, 21, 22	A0, A2, A1	0V	100k $\Omega$ resistor to GND
23, 24, 25	LE, CLK, DATA	2.5V	100k $\Omega$ pull-up resistor to internally regulated 2.5V
26 – 32	D6 – D0	2.5V	100k $\Omega$ pull-up resistor to internally regulated 2.5V
