### GENERAL DESCRIPTION

The **AD9081** mixed signal front end (MxFE®) is a highly integrated device with four 16-bit, 12 GSPS maximum sample rate, RF digital-to-analog converter (DAC) cores, and four 12-bit, 4 GSPS rate, RF analog-to-digital converter (ADC) cores. The AD9081 is well suited for applications requiring both wideband ADCs and DACs to process signal(s) that have wide instantaneous bandwidth. The device features eight transmit and eight receive lanes that support 24.75 Gbps/lane JESD204C or 15.5 Gbps/lane JESD204B standards. The device also has an on-chip clock multiplier, and a digital signal processing (DSP) capability targeted at either wideband or multiband direct to RF applications. The DSP datapaths can be bypassed to allow a direct connection between the converter cores and the JESD204 data transceiver port. The device also features low latency loopback and frequency hopping modes targeted at phase array radar system and electronic warfare applications. Two models for the AD9081 are offered. The 4D4AC model supports the full instantaneous channel bandwidth, whereas the 4D4AB model supports a maximum instantaneous bandwidth of 600 MHz per channel by automatically configuring the DSP to limit the instantaneous bandwidth at startup. See the [Ordering Guide](#) for more information.

<sup>1</sup> The values listed for these parameters are the maximum possible when considering all JESD204 modes of operation. Some modes are more limiting, based on other parameters.

<sup>2</sup> The interpolation filters in the Tx datapath have a total complex filter bandwidth of 80% of the data rate, combining the 40% bandwidth in the I path and 40% bandwidth in the Q path. Similarly, the decimation stages inside the Rx datapath use filters with a total complex filter bandwidth of 81.4%. Therefore, the maximum allowed instantaneous complex signal bandwidth (iBW) per channel is calculated as  $iBW = (\text{complex I/Q data rate per channel}) \times (\text{total complex filter bandwidth})$ .

Parameter	3 GSPS			4 GSPS			Unit
	Min	Typ	Max	Min	Typ	Max	
ANALOG BANDWIDTH <sup>4</sup>		7.5			7.5		GHz

<sup>1</sup> Noise density is measured at 250 MHz input frequency at -30 dBFS, where timing jitter does not degrade noise floor.

<sup>2</sup> Noise figure is based on a nominal full-scale input power of 4.5 dBm with an input span of 1.4 V p-p and  $R_{IN} = 100 \Omega$ .

<sup>3</sup> With background interleaving calibration converged.

<sup>4</sup> Analog input bandwidth is the bandwidth of operation in which the full-scale input frequency response rolls off by -3 dB based on a de-embedded model of the ADC extracted from the measured frequency response on evaluation board. This bandwidth requires optimized matching network to achieve this upper bandwidth.

<sup>1</sup> Tested continuously for 1000 hours with  $f_{IN} = 4.7$  GHz pulsed and continuous tone at maximum allowed junction temperature (T<sub>J</sub>). Refer to the [UG-1578](#) user guide for more information.

<sup>2</sup> Do not exceed this temperature for any duration of time when the device is powered.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

Thermal performance is directly linked to PCB design and operating environment. The use of appropriate thermal management techniques is recommended to ensure that the maximum T<sub>J</sub> does not exceed the limits shown in [Table 19](#).

θ<sub>JA</sub> is the natural convection, junction to ambient thermal resistance measured in a one cubic foot sealed enclosure.

θ<sub>JC\_TOP</sub> is the junction to case, thermal resistance.

θ<sub>JB</sub> is the junction to board, thermal resistance.

<sup>1</sup> Thermal resistance values specified are simulated based on JEDEC specifications in compliance with JESD51-12 with the device power equal to 9 W.

## ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## THEORY OF OPERATION

The AD9081 is a highly integrated, 28 nm, RF, MxFE featuring four 16-bit, 12 GSPS DAC cores and four 12-bit, 4 GSPS ADC cores (see [Figure 1](#)). The DAC core is based on a current segmentation architecture providing a differential complementary current output with an adjustable  $I_{OUTFS}$  range of 6.43 mA to 37.75 mA. The ADC core is based on a proprietary interleaved architecture that suppresses residual interleaving spurious products into the noise floor. To enable wide bandwidth operation, a high linearity, 100  $\Omega$  differential buffer with overload protection is used to isolate the ADC core from the RF ADC driver source. An on-chip clock multiplier can be used to synthesize the RF DAC and ADC clocks. Alternatively, an external clock can be applied.

Flexible transmit and receive DSP paths are available to up sample and down sample the desired intermediate frequency (IF) and RF signal(s) to lower the required data interface rates and efficiently align with bandwidth requirements. The channelizer data path enables efficient data transfer to allow multiband applications where up to eight unique RF bands are supported. The transmit and receive DSP paths are symmetric and consist of four coarse digital upconversion (DUC) and digital downconversion (DDC) blocks in the main data path along with eight fine DUC and DDC blocks in the channelizer data path. Each DUC and DDC block includes multiple interpolation or decimation stages and a 48-bit NCO configurable for integer or fractional mode of operation. The NCOs in the coarse DUC and DDC block support fast frequency hopping, coherently, and can be controlled using GPIOs. The DUC blocks, the DDC blocks, and the data paths can be fully bypassed to enable Nyquist operation.

Various auxiliary DSP features facilitate an improved system integration. The data paths include adjustable delay lines to compensate for mismatch in channel delay paths that may occur external

to the device. The transmit data path includes digital gain control, fine delay adjust, and power amplifier protection to simplify DPD integration in a multiband transmitter. The receive data path includes a flexible, programmable, 192-tap finite impulse response (PFIR) filter. This filter can be allocated across one or more ADCs for receive equalization with support for four different profiles. The profiles can be selected using the GPIOx pins. The receive data path also includes a fast and slow signal detection capability in support of automatic gain control (AGC). The data paths also include features to reduce power consumption in time division duplex (TDD) applications. All the auxiliary DSP features can be fully bypassed.

The AD9081 also supports a low latency digital loopback between the receive and transmit data paths to bypass the JESD204 link. The data formatting of the data paths can be real or complex (I/Q) with selectable resolutions of 8, 12, 16, and 24 bits, depending on the JESD204B or the JESD204C mode.

A 16-lane JESD204 transceiver port is available to support the high data throughput rates on the receive and transmit data paths. Eight SERDES lanes are designated for the transmit data paths, whereas the other eight lanes are designated for the receive data paths. The transceiver port supports JESD204C up to 24.75 Gbps, or JESD204B up to 15.5 Gbps lane rates. The JESD204 data link layer is highly flexible, allowing to adjust the lane count (or rate) required to support a target link throughput. An external alignment signal (SYSREF) can be used to guarantee deterministic latency, phase alignment, and aid in multichip synchronization.

An on-chip thermal management unit (TMU) can be used to measure the die temperature as part of a thermal management solution to guarantee better thermal stability during system operation.
