Functional Description

CY62167G30 and CY62167GE30 are high-performance CMOS, low-power (MoBL[®]) SRAM devices with embedded ECC^[2]. Both devices are offered in single and dual chip enable options and in multiple pin configurations. The CY62167GE30 device includes an ERR pin that signals a single-bit error-detection and correction event during a read cycle.

To access devices with a single chip enable input, assert the chip enable (\overline{CE}) input LOW. To access dual chip enable devices, assert both chip enable inputs – \overline{CE}_1 as LOW and CE_2 as HIGH.

To perform data writes, assert the Write Enable (\overline{WE}) input LOW, and provide the data and address on the device data pins (I/O_0

through I/O_{15}) and address pins (A_0 through A_{19}) respectively. The Byte High Enable (\overline{BHE}) and Byte Low Enable (\overline{BLE}) inputs control byte writes and write data on the corresponding I/O lines to the memory location specified. \overline{BHE} controls I/O_8 through I/O_{15} and \overline{BLE} controls I/O_0 through I/O_7 .

To perform data reads, assert the Output Enable (\overline{OE}) input and provide the required address on the address lines. You can access read data on the I/O lines (I/O_0 through I/O_{15}). To perform byte accesses, assert the required byte enable signal (\overline{BHE} or \overline{BLE}) to read either the upper byte or the lower byte of data from the specified address location.

All I/O s (I/O_0 through I/O_{15}) are placed in a high-impedance state when the device is deselected (\overline{CE} HIGH for a single chip enable device and \overline{CE}_1 HIGH/ CE_2 LOW for a dual chip enable device), or the control signals are de-asserted (\overline{OE} , \overline{BLE} , \overline{BHE}).

These devices have a unique Byte Power-down feature where, if both the Byte Enables (\overline{BHE} and \overline{BLE}) are disabled, the devices seamlessly switch to the standby mode irrespective of the state of the chip enables, thereby saving power.

On the CY62167GE30 devices, the detection and correction of a single-bit error in the accessed location is indicated by the assertion of the ERR output (ERR = High). See the Truth Table – CY62167G30/CY62167GE30 on page 15 for a complete description of read and write modes.

The CY62167G30 and CY62167GE30 devices are available in a Pb-free 48-pin TSOP I package and 48-ball VFBGA packages. See the Logic Block Diagram – CY62167G30 on page 2.

The device in the 48-pin TSOP I package can also be configured to function as a 2M words × 8 bit device. Refer to the Pin Configurations section for details.

Notes

28. Test conditions assume signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for $V_{CC} \geq 3$ V) and $V_{CC}/2$ (for $V_{CC} < 3$ V), and input pulse levels of 0 to 3 V (for $V_{CC} \geq 3$ V) and 0 to V_{CC} (for $V_{CC} < 3$ V). Test conditions for the read cycle use the output loading shown in Figure 6 on page 8, unless specified otherwise.
29. At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZBE} is less than t_{LZBE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any device.
30. Tested initially and after any design or process changes that may affect these parameters.
31. t_{HZOE} , t_{HZCE} , t_{HZBE} , and t_{HZWE} transitions are measured when the outputs enter a high-impedance state.
32. These parameters are guaranteed by design and are not tested.
33. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE}_1 = V_{IL}$, \overline{BHE} or \overline{BLE} or both = V_{IL} , and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.
34. The minimum write cycle pulse width for Write Cycle No. 1 (\overline{WE} Controlled, \overline{OE} LOW) should be equal to the sum of t_{HZWE} and t_{SD} .

Notes

52. This pin is available only in the 48-pin TSOP I package. Tie the $\overline{\text{BYTE}}$ to V_{CC} to configure the device in the 1M × 16 option. The 48-pin TSOP I package can also be used as a 2M × 8 SRAM by tying the $\overline{\text{BYTE}}$ signal to V_{SS}.

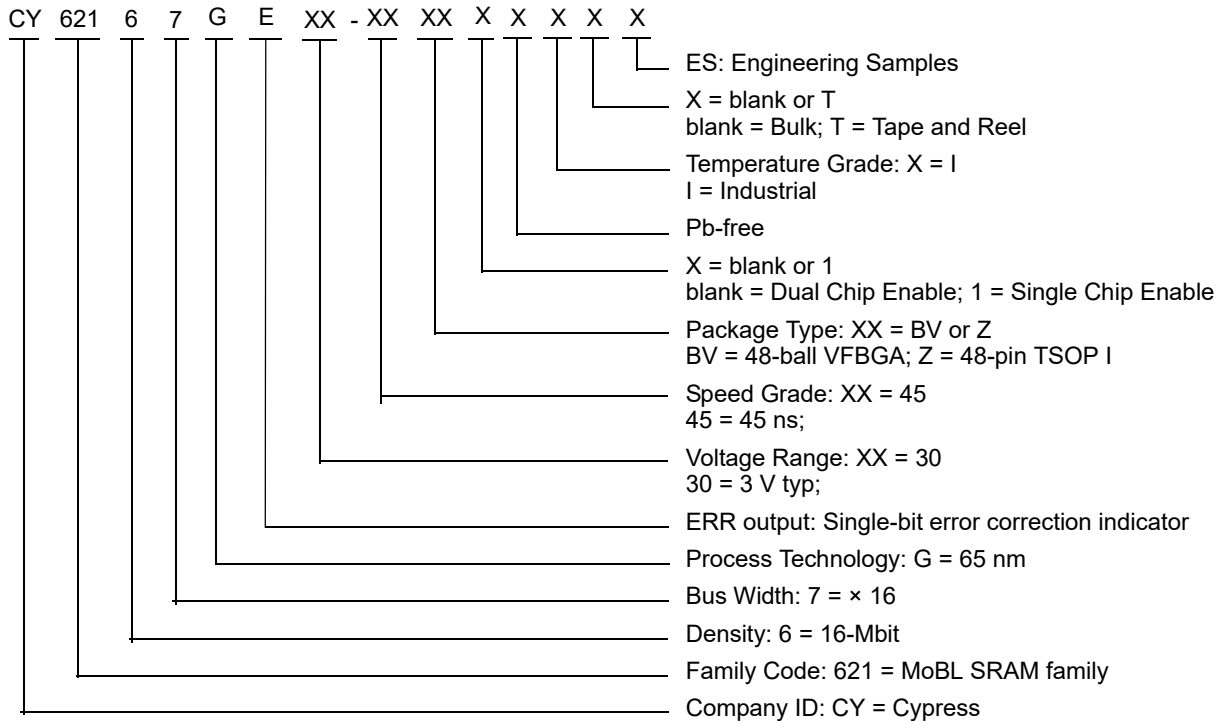

53. The 'X' (Don't care) state for the chip enables refer to the logic state (either HIGH or LOW). Intermediate voltage levels on these pins is not permitted.

54. ERR is an Output pin. If not used, this pin should be left floating.
